Dimension reduction introduction

The burn-up problem Hypothesis, data, model and idea Dimension reduction methods Efficient Global Optimization Numerical results

Initial model How and what for

# Initial model

Consider some input  $X$  define on a given space :  $\mathbb{R}^p$ ,  $L^2([0,1]), L^2(\Omega \times [0,1]).$ 

Eventually this input is linked to an output *Y* via an unknown function *f*.

 $Y = f(X)$ 

イロメ イ押 メイヨメ イヨメ

ă,  $QQ$  Dimension reduction introduction

The burn-up problem Hypothesis, data, model and idea Dimension reduction methods Efficient Global Optimization Numerical results

How and what for

# How and what for

Goal :

- **•** find a sub-space on which the initial input can be projected without or with a minimum loss of information
	- independently of the output (unsupervised learning).
	- guided by the output (supervised learning).
- Methods :
	- Selection : eliminate the input dimensions which do not explain the phenomenon under study (sensitivity analysis, LASSO...)
	- Extraction : optimally reorganized the information carried by the input with regard or not to an observable output  $(ACP, SIR...)$ メロメメ 御きメ ミトメ ヨメー

#### Industrial context Optimization problem Burn-up profil treatment

# **Context**

Crayon après cycle de vie dans le réacteur nucleaire. On considère le taux de combustion mesuré en Megawatt-jour/tonnes sur l'axe verticale du crayon

# **Context**

Industrial context Optimization problem Burn-up profil treatment

In nuclear power technology, burnup (also known as fuel utilization) is a measure of how much energy is extracted from a nuclear fuel assembly. It is measured both as the actual energy released per mass of initial fuel in gigawatt-days/metric ton of heavy metal (GWd/tHM)

K ロ ⊁ K 個 ≯ K 君 ⊁ K 君 ⊁

 $2Q$ 

Industrial context Optimization problem Burn-up profil treatment

# The optimization problem

As the criticality coefficient depends on the combustion rate, identify the most penalizing rate leads to solve the following inverse optimization problem :

$$
x^* = \underset{x \in V}{\operatorname{argmax}} \ f(x). \tag{1}
$$

 $\left\{ \begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \end{array} \right.$ 

 $\Omega$ 

where  $\mathsf{V}\subset L^2(\Omega\times [0,1])$  is a normed linear functional space.

To ensure the existence of the maximum and for the problem (1) to be well posed, some suitable hypothesis on the functional *f* and the set *V* should be verified (semicontinuity, compacity...).

The stochastic process Smoothing/Projecting data The algorithm

 $290$ 

# The algorithm

- Data as discretized functional data
- Smoothing data : B-spline or Wavelet, estimate decomposition coefficients and parameters
- $\bullet$  Find,  $\beta$ 's, the reduced space base functions : PCA, MAVE, SIR
- Sample a number of curves in the previous basis, i.e. sample a number of coordinates  $\theta$ 's
- Run EGO algorithm on the model with inputs the  $\theta$ 's + (\*)
- Transpose the found optimal  $\theta^*$  onto the 'smooth' functional space
- (∗) Transform the obtained smooth function into the considered data (piecewise) K ロ ⊁ K 個 ≯ K 君 ⊁ K 君 ⊁

Process parameters and empirical approximations Functional Principal Component analysis (FPCA) Wavelet Sliced Inverse Regression (WSIR) Wavelet Minimum Average Variance Estimation (WMAVE)

イロメ イ押 メイヨメ イヨメ

 $2Q$ 

# The empirical approximations

For any  $s,t \in [0,1]$  and  $v \in L^2[0,1]$ , we suppose and denote :

$$
\bullet \ \mu(t) = \mathbb{E}(X(t)) = 0
$$

$$
\bullet \ \sigma^2(t) = \mathbb{E}\big(X(t)^2\big)
$$

$$
\bullet \ \gamma(t,s) = \mathbb{E}\big(X(t)X(s)\big)
$$

$$
\bullet\;(\Gamma v)(t)=\int_0^1\gamma(t,s)v(s)ds
$$

We consider the empirical estimators :

$$
\hat{\sigma}^2(t) = (n-1)^{-1} \sum_{i=1}^n X_i(t)^2 = (n-1)^{-1} \mathbf{X}(t)^2
$$

• 
$$
\hat{\gamma}(t,s) = (n-1)^{-1} \sum_{i=1}^{n} X_i(t)X_i(s) = (n-1)^{-1} \mathbf{X}'(t) \mathbf{X}(s)
$$

$$
\bullet \;(\hat{\Gamma}v)(t)=\int_0^1\hat{\gamma}(t,s)v(s)ds
$$
