## Context

### Design of Experiments (DoEs) :

- Used in exploration, optimization and uncertainty quantification, when coupled with time-consuming numerical simulators
- Aim : select a **limited number** of values to assign to the simulator input variables that give a **maximal knowledge** on the simulator outputs of interest

## Context

- Vast literature on space-filling DoEs for continuous variables
- Less extensive for mixed continuous and discrete variables

**Objective 1 : Propose space-filling DoE in mixed continuous and discrete space :**

$$\mathcal{D} = \{z = (x, y) \in \mathbb{R}^m \times \mathbb{I}^n\}. \quad (1)$$

- DoEs are applied to integer encoding of discrete variables

**Objective 2 : Relevant DoEs for a large range of applications**

## Literature review

- Extended work from LHS for continuous to mixed variables : independent Latin Hypercubes (**Santner2003**), Sliced Latin Hypercube (**Quian2012**)

Require large numbers of points to obtain a space-filling DoE  
⇒ Not reasonable for expensive simulators !

- In derivative-free optimization context : rounding LHS (R-LHS) (**Costa2018**), i.e. a classical LHS for relaxed integer variables, then values are rounded to obtain discrete values

Duplicated points

## Literature review

- Projected DoEs : based on the projection of continuous values to integers representing the indices of discrete variables
- Example : generate DoE with 4 integers  $\in \{1,2,\dots,8\}$

- Coupled with various DoEs : LHS, Sobol sequences (A-LHS, A-Sobol)

No prior information is used, e.g., cyclic symmetry, periodicity, correlations,...

### Objective 3 : DoEs taking into account some given **prior** information

## Outline

**1** Two new DoE methods for mixed discrete variables

**2** Numerical results

**3** Conclusions

## Table of Contents

**1** Two new DoE methods for mixed discrete variables

**3** Conclusions

## Problem statement

Select a **limited** number of values to assign to the simulator input variables that give a **maximal** knowledge of the mixed space under study :

$$\mathcal{D} = \{z = (x, y) \in \mathbb{R}^m \times \mathbb{I}^n\},$$

where  $x \in \mathbb{R}^m$ ,  $y \in \mathbb{I}^n$  are the continuous and discrete variables, respectively, and  $\mathbb{I}$  denotes the discrete space (e.g. integer, binary or categorical variables)

## Space-filling DoEs for mixed continuous and discrete variables

- We do not want

- We want well distributed points in both continuous and discrete domains

## Space-filling DoEs for continuous variables

Based on different criteria :

- Geometrical criteria :
  1. Minimax DoE : minimize the maximal distances between any points and DoE points
  2. Maximin DoE : maximize the minimal distance
- Low discrepancy criterion of the DoE points
- Kernel-embedding of distributions

**Objective : extend DoEs based on kernel-embedding distributions to mixed discrete variables**

## DoEs based on kernel-embedding distribution (I)

Main idea :

- Based on kernel-embedding of probability distributions, (**Hickernell1998**)
- Minimization of the **maximum mean discrepancy (MMD)** between an **empirical measure corresponding to the DoE** and a **target distribution**

Principle :

- A set of candidate points from the target distribution  $X = \{x_1, x_2, \dots, x_N\}$ ,  $N$  is large
- Aim : Approximate  $X$  by a subset of points  $\bar{X} = \{\bar{x}_1, \bar{x}_2, \dots, \bar{x}_{nDoE}\} \subset X, nDoE \ll N$

## Kernel herding : illustration

**Figure** – Illustration of kernel herding applied to a mixture of Gaussian for continuous variables (Chen2010)

## DoEs based on kernel-embedding distribution (II)

The problem is solved by minimizing  $\text{MMD}^2(\mathbb{P}_X, \mathbb{P}_{\tilde{X}})$  :

$$\min_{\tilde{x}_1, \tilde{x}_2, \dots, \tilde{x}_{nDoE}} \text{MMD}^2 \left( \frac{1}{N} \sum_{i=1}^N \delta_{x_i}, \frac{1}{nDoE} \sum_{j=1}^{nDoE} \delta_{\tilde{x}_j} \right),$$

where the MMD is defined as follows :

$$\text{MMD}^2(\mathbb{P}_X, \mathbb{P}_{\tilde{X}}) = \|\mu_{\mathbb{P}_X} - \mu_{\mathbb{P}_{\tilde{X}}}\|_{\mathcal{H}_k}^2,$$

with  $\mathcal{H}_k$  a Reproducing Kernel Hilbert Space (RKHS),  $k$  a **positive definite (p.d) kernel** and  $\mu_{\mathbb{P}} = \int k(x, \cdot) d\mathbb{P}(x)$  the kernel embedding of the probability distribution  $\mathbb{P}$ .

## DoEs based on kernel-embedding distribution (III)

- Interestingly, the RKHS framework allows to simplify MMD into :

$$\text{MMD}^2(\mathbb{P}_X, \mathbb{P}_{\bar{X}}) = \mathbb{E}_{\xi, \xi' \sim \mathbb{P}_X} k(\xi, \xi') + \mathbb{E}_{\zeta, \zeta' \sim \mathbb{P}_{\bar{X}}} k(\zeta, \zeta') - 2\mathbb{E}_{\xi \sim \mathbb{P}_X, \zeta \sim \mathbb{P}_{\bar{X}}} k(\xi, \zeta).$$

- The Kernel herding approach is a greedy sequential algorithm to solve the minimization problem (Chen2010) :

$$\bar{x}_1^* = \operatorname{argmax}_{\bar{x} \in X} \frac{1}{N} \sum_{j=1}^N k(\bar{x}, x_j).$$

For  $t = 1, \dots, nDoE - 1$  :

$$\bar{x}_{t+1}^* = \operatorname{argmax}_{\bar{x} \in X} \frac{1}{N} \sum_{j=1}^N k(\bar{x}, x_j) - \frac{1}{t+1} \sum_{i=1}^t k(\bar{x}, \bar{x}_i^*).$$

- The current kernel herding algorithm only considers kernels for continuous variables
- The requirement of p.d kernel can be difficult to extend to mixed discrete variables
- **Our proposal : We focus on cases where a distance for discrete variables is already defined** (which will also account for prior information)

## Extending kernel herding to mixed variables

- Two proposals to use this distance inside kernel herding
  1. We build a continuous encoding of the discrete variables. The original kernel herding algorithm with a standard p.d continuous kernel is then used in this transformed space
  2. We directly define a p.d kernel for mixed discrete variables which is integrated inside kernel herding

## First proposal : *Greedy-MDS* approach

- Main idea : we build a continuous encoding of discrete variables
  1. We compute all the pairwise distances in the discrete space for the large sample from the target
  2. We apply Multidimensional Scaling (MDS), (**Kruskal1964**), to this distance matrix  $\Rightarrow$  a continuous representation of discrete variables
  3. We build the target distribution in this transformed space by completing the encoded distribution of the original discrete variables with a sliced space filling design for continuous variables
  4. We apply kernel herding with a classical kernel for continuous variables, e.g. Gaussian kernel
  5. We retrieve the final DoE by "de-encoding" the selected samples into the original discrete values (thanks to the MDS correspondence)

## Second proposal : *Adapted-Greedy* approach

- Main idea : we directly integrate an appropriate kernel for mixed discrete variables inside kernel herding
- This requires a p.d kernel for mixed continuous and discrete variables
- Adapt kernel to application which accounts for the prior information on mixed variables, e.g., symmetry, correlations,...

Relevant approach for a large range of applications

- Two examples :
  1. The mixed continuous and binary kernel (Hutter2014), no prior information
  2. The soft string kernel (Wu2019) which is defined from any distance, thus being able to include a prior

## Specific kernels

- Mixed continuous and **binary** kernel (**Hutter2014**)

$$K_{mixed}^H(z_i, z_j) = \exp\left(-\lambda_c \cdot \|x_i - x_j\|^2 - \lambda_b d_H(y_i, y_j)\right),$$

$d_H$  the Hamming distance, hyper-parameters  $\lambda_b = n$  and  $\lambda_c$  computed thanks to the rule of thumb :

$$\lambda_c = \lambda_b \frac{\text{median}(d_H(y_i, y_j))}{\text{median}(\|x_i - x_j\|_2^2)}. \quad (2)$$

- The soft string kernel (**Wu2019**)

$$k^{soft}(y_i, y_j) = \sum_{\omega \in \Omega} e^{-\gamma \{d(y_i, \omega) + d(y_j, \omega)\}},$$

$d$  is a user-defined distance. Hence we propose a **mixed soft string kernel** :

$$K_{mixed}^{soft}(z_i, z_j) = \exp\left(-\lambda_c \cdot \|x_i - x_j\|^2\right) k^{soft}(y_i, y_j),$$

hyper-parameters  $\lambda_c, \gamma$  are chosen as above.

## Illustrations of our adapted-greedy approach

- Problem with 1 continuous variable, 1 categorical variable with 14 levels

Figure – DoE obtained by adapted-greedy approach

## Table of Contents

**1** Two new DoE methods for mixed discrete variables

**2** Numerical results

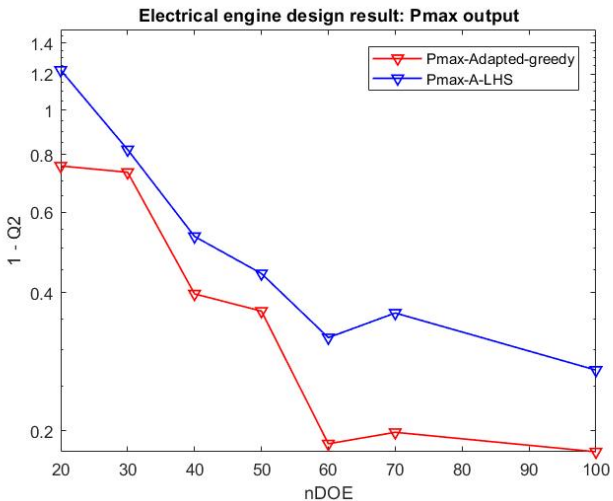

**3** Conclusions

## DoEs for mixed continuous and discrete variables

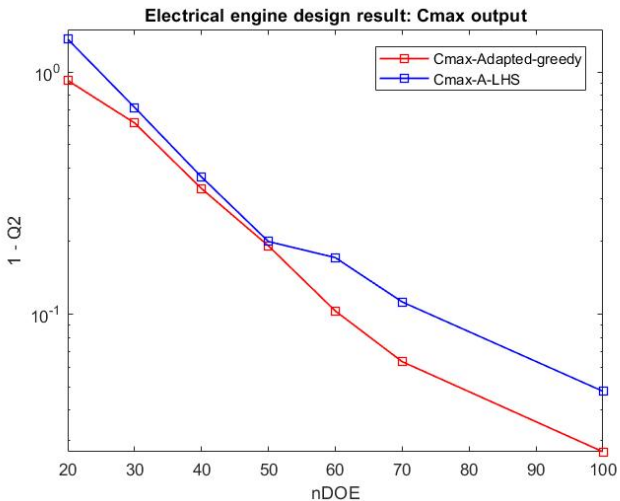

### Example 1 : we use a DoE to build a surrogate model

- Test case : the maximal torque ( $C_{max}$ ) and the maximal power ( $P_{max}$ ) of an electrical engine
- Inputs : 1 categorical (rotor type), 2 integer (number of wires and coils) and 1 continuous variables (length of the rotor). We encode all discrete variables as binary ones
- We compare two DoE methods : kernel herding approach (Adapted Greedy), projected LHS (A-LHS)
- We use the p.d. kernel proposed by (**Hutter2014**)
- The surrogate model is a kriging model with adapted mixed discrete kernel, (**Qian2008**)

## Numerical results for DoEs with mixed discrete variables

## Numerical results for DoEs with mixed discrete variables

## DoEs for mixed continuous and binary variables with cyclic symmetry property (I)

**Example 2** : we build a DOE to approximate the mean of a function with symmetrical inputs

- We assume that the input variables are binary arrangements invariant by rotation : concept of **necklace**, e.g. 1001 ~ 1100 ~ 0110...

- In (Tran2021), we proposed the *necklace distance* :

$$d_{neck}(y, y') = \min_{i=1,2,\dots,n} d_H(y, Rot^i(y'))$$

## DoEs for mixed continuous and binary variables with cyclic symmetry property (II)

- Tested functions :  $\sin(\|\cdot\|)$ , Branin, Hartman3, Perm6 transformed into cyclic symmetry problems

Functions	$m \times n$	# necklaces
$\sin(\ \cdot\ )$	$2 \times 7$	20
Branin	$1 \times 7$	20
Hartman3	$3 \times 6$	14
Perm6	$5 \times 5$	10

- RMSE of the mean of the function for each necklace  $F_i(\cdot)$  :

$$\text{RMSE}(\delta_{nDoE}) = \sqrt{\frac{1}{n_{neck}} \sum_{i=1}^{n_{neck}} \left( F_i(X_{ref}^i) - F_i(\delta_{nDoE}^i) \right)^2},$$

$n_{neck}$  is the number of distinct necklaces,  $\delta_{nDoE}^i, i = 1, 2, \dots, n_{neck}$  are the DoE points for a given necklace  $i$

# Mixed continuous and binary with cyclic symmetry property : results

$$nDoE = kn_{neck}$$

## Table of Contents

**1** Two new DoE methods for mixed discrete variables

**2** Numerical results

**3** Conclusions

## Conclusions and perspectives

### ■ Main results

1. Extended DoEs to mixed discrete variables thanks to kernel herding approach
2. Different p.d kernels adapted to the type of problems
3. Promising results for various types of mixed discrete problems

### ■ Perspectives

1. Enlarge the application domain of our DoE methods, e.g., other objects as time series, images...with adapted kernels

## Perspectives : time series applications

**Objective : build DOEs for a functional variable to compute the mean of a function**

- Applied to Max-stable curves (200)
- DoEs methods : Reduced LHS (LHS + PCA),  $L_2$  greedy quantization method (L2 quantization + PCA) (**EIAmri2019**), adapted-greedy
- Kernel : normalized global alignment kernel, (**Cuturi2007**)
- Measure the expectation estimation errors of function

$$f : V \rightarrow \max_t V_t |0.1 \cos(a \max_t V_t) \sin(b)(a + b \min_t V_t)|^2 \int_0^T (30 + V_t)^{\frac{ab}{20}} dt, a = 2.95, b = 3.97$$

## DoEs for time series : kernel

Kernel used in adapted-greedy approach : the normalized global alignment kernel for same length time series, **Cuturi2007** :

$$K^{GAK}(V_1, V_2) = K(V_1, V_2) - \frac{1}{2}(K(V_1, V_1) + K(V_2, V_2)) \quad (3)$$

where  $K$  is the global alignment kernel

$$K(V_1, V_2) = \prod_{i=1}^{|V_2|} e^{-\phi_\sigma(V_1^i, V_2^i)} \quad (4)$$

with

$$\phi_\sigma(V_1^i, V_2^i) = \frac{1}{2\sigma^2} \|V_1^i - V_2^i\|^2 + \log(2 - e^{-\frac{\|V_1^i - V_2^i\|^2}{2\sigma^2}})$$

## Preliminary results on time series

- Adapted-greedy is competitive with other methods
- L2 quantization method requires a preliminary step of dimension reduction
- Adapted-greedy gains in terms of CPU time

## DoEs for mixed continuous and binary variables with cyclic symmetry property

## Objective : build DOE to compute the mean of a function

- Tested functions :  $\sin(\|x\|)$ , Branin, Hartman3, Perm6
- Build cyclic symmetry property function : restrict the last continuous variable to take only a finite number of values in the discretized-interval set :

$$X^{end} := \left\{ \underline{x}^{end} + (w-1) \frac{\bar{x}^{end} - \underline{x}^{end}}{l-1} : w = 1, 2, \dots, l \right\}$$

- Each level corresponds to a distinct binary arrangement of size  $n$ , for example

$$\min_{x \in [\underline{x}, \bar{x}], y \in \{0,1\}^2} f(x, y) := \begin{cases} F(x, 1), & \text{if } y = (0, 0) \\ F(x, 2), & \text{if } y = (0, 1), (1, 0) \\ F(x, 3), & \text{if } y = (1, 1) \end{cases} \quad (5)$$
