A Probabilistic constraint is a constraint of the type

$$\varphi(x) := \mathbb{P}[g(x,\xi) \le 0] \ge p, \tag{1}$$

where  $g: \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^k$  is a map,  $\xi \in \mathbb{R}^m$  a (multi-variate) random variable

- Such constraints arise in many applications. For instance cascaded Reservoir management.
- We care for further understanding of differentiability of probability functions

Some differentiability properties of PCs I						

General differentiability statements exist and represent the gradient as an involved integral over a "surface" and "volume". A key condition is that  $\{z \in \mathbb{R}^m : g(x, z) \le 0\}$  is bounded locally around a point x (e.g., [Uryas'ev(2009)]).

### Some differentiability properties of PCs II

Specific formulas such as the following, allow for efficient computation in practice:

#### Lemma ([Prékopa(1970), Prékopa(1995)])

Let  $\xi$  be an *m*-dimensional Gaussian random vector with mean  $\mu \in \mathbb{R}^m$  and positive definite variance-covariance matrix  $\Sigma$ . Then the distribution function  $F_{\xi}(z) := \mathbb{P}[\xi \leq z]$  is continuously differentiable and in any fixed  $z \in \mathbb{R}^m$  the following holds:

$$\frac{\partial F_{\xi}}{\partial z_{i}}(z) = f_{\xi_{i}}(z_{i})F_{\tilde{\xi}(z_{i})}(z_{1},...,z_{i-1},z_{i+1},...,z_{m}), i = 1,...,m.$$
(2)

Here  $\tilde{\xi}(z_i)$  is a Gaussian random variable with mean  $\hat{\mu} \in \mathbb{R}^{m-1}$  and  $(m-1) \times (m-1)$  positive definite covariance matrix  $\hat{\Sigma}$ . Let  $D_m^i$  denote the mth order identity matrix from which the ith row has been deleted. Then  $\hat{\mu} = D_m^i(\mu + \Sigma_{ii}^{-1}(z_i - \mu_i)\Sigma_i)$  and  $\hat{\Sigma} = D_m^i(\Sigma - \Sigma_{ii}^{-1}\Sigma_i\Sigma_i^{\mathsf{T}})(D_m^i)^{\mathsf{T}}$ , where  $\Sigma_i$  is the *i*-th column of  $\Sigma$ .

Setting				
Setting				

Consider the probabilistic constraint :

$$\varphi(\mathbf{x}) := \mathbb{P}[g(\mathbf{x},\xi) \le \mathbf{0}] \ge \mathbf{p},\tag{3}$$

where  $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^p$  is a continuously differentiable map (convex in the second argument),  $\xi \sim \mathcal{N}(\mu, \Sigma)$  a (multi-variate) Gaussian random variable.

	Differentiability: setting O● ○○○○○ ○○○	Differentiability: results 0000 00000000	(Sub-)Differentiability 000 0000000000 0000	
Setting				
Motivation				

We would like to dispose of a gradient formulae for the case

 $\varphi(\mathbf{x}) := \mathbb{P}[\langle \mathbf{c}, \eta \rangle \leq h(\mathbf{x})],$ 

where  $c \ge 0, c \in \mathbb{R}^m$ , and  $\eta \in \mathbb{R}^m$  is a log-normal random variable

We can cast this into the general case by defining the mapping

$$g(x,z) = \langle c, \exp(z) \rangle - h(x)$$

• Then  $\varphi(x) = \mathbb{P}[g(x,\xi) \leq 0]$  with  $\xi \sim \mathcal{N}(\mu, \Sigma)$ .

In fact by redefining g we may assume w.l.o.g. that  $\xi \sim \mathcal{N}(0, R)$ .

	Differentiability: setting	Differentiability: results		
	00 • <b>0000</b> 000	0000 0000000	000 0000000000 0000	
Inherent non-smooth	iness			

Inherent non-smoothness

- It is tempting to believe that "nice" properties of g carry forth to φ. For instance, if g is smooth enough, that φ will be at least continuously differentiable.
- Though "nasty laws" for ξ can be expected to have side-effects, nice laws may not.
- Let us first show that such considerations are dangerous.

	Differentiability: setting ○○ ○●○○○ ○○○	Differentiability: results 0000 00000000	(Sub-)Differentiability 000 0000000000 0000			
Inherent non-smoothness						
Inherent non-smoothness: counterexample						

Differentiability need not hold:

Proposition

Let  $g:\mathbb{R}^2\times\mathbb{R}^2\to\mathbb{R}$  be defined by

 $g(x_1, x_2, z_1, z_2) := x_1^2 e^{h(z_1)} + x_2 z_2 - 1$ , where  $h(t) := -1 - 2\log(1 - \Phi(t))$ 

and  $\Phi$  is the cumulative distribution function of the one-dimensional standard Gaussian distribution. Let  $\xi \sim \mathcal{N}(0, l_2)$  and  $\bar{x} = (0, 1)$ . Then, the following holds true:

- 1 g is continuously differentiable.
- 2 g is convex in the second argument.
- 3  $g(\bar{x},0) = g(0,1,0,0) < 0.$
- 4  $\varphi$  is not differentiable at  $\bar{x}$ .

	Differentiability: setting	Differentiability: results		
	00 00●00 000	0000 0000000	000 0000000000 0000	
Inherent non-smoothness				

### Inherent non-smoothness: counterexample

Graph of a non-differentiable probability function

	Differentiability: setting	Differentiability: results		
	00 00000 000	0000 0000000	000 0000000000 0000	
Inherent non-smoot	hness			

### Inherent non-smoothness: several components

Things may also go wrong when p > 1, i.e., g has several components:

#### Example

Let  $\xi$  have a one-dimensional standard Gaussian distribution and define

$$g(x_1, x_2, x_3, \xi) := (\xi - x_1, \xi - x_2, -\xi - x_3).$$

Then, with  $\Phi$  referring to the one-dimensional standard Gaussian distribution function, one has that

$$\varphi(x_1, x_2) = \max\{\min\{\Phi(x_1), \Phi(x_2)\} - \Phi(x_3), 0\}.$$

Clearly  $\varphi$  fails to be differentiable at  $\bar{x} := (0, 0, -1)$ , while  $\{z : g(\bar{x}, z) \le 0\} = [-1, 0]$  is compact and satisfies Slater's condition in the description via g.

Inherent non-smoothness

### Inherent non-smoothness: the need for additional conditions

- From these discussion it is clear that some conditions needs to be appended in order to avoid some degeneracy
- Essentially two conditions are needed: bounded growth on  $\nabla_x g$ , some LICQ type of regularity.

	Differentiability: setting	Differentiability: results

#### Theorem ([van Ackooij and Henrion(2014)])

Let  $g : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$  be a continuously differentiable function which is convex with respect to the second argument. Consider the probability function  $\varphi$  defined as  $\varphi(x) = \mathbb{P}[g(x,\xi) \leq 0]$ , where  $\xi \sim \mathcal{N}(0,R)$  has a standard Gaussian distribution with correlation matrix R. Let the following assumptions be satisfied at some  $\bar{x}$ :

1  $g(\bar{x}, 0) < 0.$ 

**2** g satisfies the exponential growth condition at  $\bar{x}$ 

Then,  $\varphi$  is continuously differentiable on a neighbourhood U of  $\bar{x}$  and it holds for all  $x \in U$  that:

$$\nabla\varphi(\mathbf{x}) = -\int_{\mathbf{v}\in F(\mathbf{x})} \frac{\chi(\rho^{\mathbf{x},\mathbf{v}}(\mathbf{x},\mathbf{v}))\nabla_{\mathbf{x}}g(\mathbf{x},\rho^{\mathbf{x},\mathbf{v}}(\mathbf{x},\mathbf{v})L\mathbf{v})}{\langle\nabla_{\mathbf{z}}g(\mathbf{x},\rho^{\mathbf{x},\mathbf{v}}(\mathbf{x},\mathbf{v})L\mathbf{v}),L\mathbf{v}\rangle} d\mu_{\zeta}(\mathbf{v}).$$

22/56

	Differentiability: setting 00 00000 000	Differentiability: results 000● 00000000
The one component	case	

Summary

#### Theorem

The previous Theorem remains true if the growth condition is replaced by the condition that the set  $\{z|g(\bar{x},z) \leq 0\}$  is bounded. Then, the formula becomes

$$\nabla\varphi(\mathbf{x}) = -\int_{\mathbf{v}\in\mathbb{S}^{m-1}} \frac{\chi(\rho^{\mathbf{x},\mathbf{v}}(\mathbf{x},\mathbf{v}))\nabla_{\mathbf{x}}g(\mathbf{x},\rho^{\mathbf{x},\mathbf{v}}(\mathbf{x},\mathbf{v})\,\mathbf{L}\mathbf{v})}{\langle\nabla_{\mathbf{z}}g(\mathbf{x},\rho^{\mathbf{x},\mathbf{v}}(\mathbf{x},\mathbf{v})\,\mathbf{L}\mathbf{v}),\mathbf{L}\mathbf{v}\rangle}d\mu_{\zeta}(\mathbf{v})$$

	Differentiability: setting	Differentiability: results

More than one comp	onent			

The case p > 1

• When p > 1 we can define

$$g^{m}(x,z) = \max_{j=1,...,p} g_{j}(x,z),$$
 (5)

Evidently, the probability function can be written as  $\varphi(x) = \mathbb{P}(g^m(x,\xi) \le 0)$ .

- For each  $x \in \mathbb{R}^n$  with g(x, 0) < 0 and  $v \in F(x)$  we can find a unique  $\rho^{x,v}(x, v) > 0$  such that  $g^m(x, \rho^{x,v}(x, v)Lv) = 0$ . However this  $\rho^{x,v}$  is no longer smooth!
- The sets of finite and infinite directions can be defined with respect to g<sup>m</sup> or alternatively as unions (intersections) of their counterparts with respect to each component of g.

	Differentiability: setting	Differentiability: results

### The case p > 1: main result

#### Theorem ([van Ackooij and Henrion(2016)])

Let the following conditions be satisfied at some fixed  $\bar{x} \in \mathbb{R}^n$ :

1 
$$g^m(\bar{x},0) < 0.$$

**2**  $g_j$  satisfies the exponential growth condition at  $\bar{x}$  for all j = 1, ..., p.

Then,  $\varphi$  is locally Lipschitz continuous on a neighbourhood U of  $\bar{x}$  and it holds that

$$\partial^{c}\varphi(x) \subseteq \int_{v \in F(x)} \operatorname{Co}\left\{-\frac{\chi(\hat{\rho}(x,v))\nabla_{x}g_{j}(x,\hat{\rho}(x,v)Lv)}{\langle \nabla_{z}g_{j}(x,\hat{\rho}(x,v)Lv),Lv \rangle}\middle| j \in \hat{\mathcal{J}}(x,v)\right\} d\mu_{\zeta}(v)$$
(6)

for all  $x \in U$ . Here,

$$\hat{\mathcal{J}}(x,v) := \{ j \in \{1, \dots, p\} | g_j(x, \hat{\rho}(x, v) \, Lv) = 0 \} \quad (v \in F(x))$$

### The case p > 1: An auxiliary result

#### Lemma ([van Ackooij and Henrion(2016)])

Let  $\bar{x} \in \mathbb{R}^n$  be given such that

1  $g^m(\bar{x},0) < 0.$ 

**2** g satisfies (R2CQ) at  $\bar{x}$ .

Then,  $\mu_{\zeta}(M') = 0$  for  $M' := \{ v \in \mathbb{S}^{m-1} | \exists r > 0 : g(\bar{x}, rLv) \leq 0, \ \#\mathcal{I}(\bar{x}, rLv) \geq 2 \}$ , where L is the regular matrix in the decomposition  $R = LL^{T}$ .

	Differentiability: setting	Differentiability: results		
	00 00000 000	0000 00000000	000 0000000000 0000	
More than one comr	opont			

### The case p > 1: smoothness

#### Theorem ([van Ackooij and Henrion(2016)])

Let the following conditions be satisfied at some fixed  $\bar{x} \in \mathbb{R}^n$ :

1 
$$g^m(\bar{x},0) < 0.$$

- **2**  $g_j$  satisfies the exponential growth condition at  $\bar{x}$  for all j = 1, ..., p.
- 3 (R2CQ) is satisfied

Then,  $\varphi$  is Fréchet differentiable at  $\bar{x}$  and the gradient formula:

$$\nabla\varphi(\bar{x}) = -\int_{v\in F(\bar{x}),\#\hat{\mathcal{J}}(\bar{x},v)=1} \frac{\chi\left(\hat{\rho}\left(\bar{x},v\right)\right)\nabla_{x}g_{j(v)}\left(\bar{x},\hat{\rho}\left(\bar{x},v\right)Lv\right)}{\left\langle\nabla_{z}g_{j(v)}\left(\bar{x},\hat{\rho}\left(\bar{x},v\right)Lv\right),Lv\right\rangle}d\mu_{\zeta}(v), \quad (10)$$

holds true.

If (R2CQ) is satisfied locally around  $\bar{x}$ , then,  $\varphi$  is continuously differentiable at  $\bar{x}$ .

Motivation and Setting	1			
Setting				

- Without loss of generality we concentrate on φ(z) = P[ξ ≤ z], with ξ ~ N(0,Σ) and Σ ≥ 0.
- We may also assume that Σ<sub>ii</sub> = 1 for all *i* without loss of generality (as otherwise either the system contains a redundant constraint (locally around *z*), or φ fails to be continuous in *z*).

### Correlation graph

#### Definition

Let  $\Sigma$  be an  $m \times m$  covariance matrix having all diagonal entries equal to 1. Let  $G(\Sigma) = (V, E)$  denote the (undirected) graph on the vertex set  $V = \{1, ..., m\}$  and with edge set  $E = E^+ \cup E^- = \{(i, j) : i \neq j, \Sigma_{ji} = 1\} \cup \{(i, j) : i \neq j, \Sigma_{ji} = -1\}$ . The graph  $G(\Sigma)$  (which may contain isolated vertices) will be called the correlation graph associated with  $\Sigma$ .

A characterization of the Clarke-subdifferential					
Correlation	graph				

- The correlation graph features Q connected components (each being either an isolated vertex or a complete subgraph (a clique)).
- Each connected component  $G^q = (V^q, E^q)$  is bipartite and can be separated into a left and right side  $L^q, R^q$ : elements within  $L^q$  are positively correlated, elements in  $L^q$  are negatively correlated to those in  $R^q$ .

### Correlation graph and z

#### Definition

Let  $G(\Sigma) = (V, E)$  be a correlation graph:

- Given an arbitrary  $z \in \mathbb{R}^m$ , we will say that *z* is *auto-referenced* if there exists an arc  $(i, j) \in E$  such that  $z_j = \sum_{ji} z_i$  (in other words, such that  $z_j = z_i$  if  $(i, j) \in E^+$  or such that  $z_j = -z_i$  if  $(i, j) \in E^-$ ).
- An auto-referenced point  $z \in \mathbb{R}^m$  will be called *changeable* if there exists  $(i,j) \in E$  such that  $z_k \geq z_i$  for all  $(k,i) \in E^+$  and  $z_k \geq -z_i$  for all  $(k,i) \in E^-$ .

The arc  $(i, j) \in E$  will occasionally be referred to as an auto-referencing (a changeable) arc with respect to z if z is auto-referenced (changeable).

### A first result

#### Theorem ([van Ackooij and Minoux(2015)])

Let  $\xi$  be an *m*-dimensional Gaussian random vector with mean  $\mu \in \mathbb{R}^m$  and covariance matrix  $\Sigma$  having all diagonal entries equal to 1. Then for arbitrary not-changeable  $z - \mu \in \mathbb{R}^m$ , the distribution function  $F_{\xi}(z) := \mathbb{P}[\xi \leq z]$  is locally Lipschitz at *z* and  $\partial^c F_{\xi}(z) = \{v\}$ , where for arbitrary *i*=1,...,*m*:

$$v_i = f_{\xi_i}(z_i) F_{\tilde{\xi}(z_i)}(z_1, ..., z_{i-1}, z_{i+1}, ..., z_m).$$
(12)

Here  $\partial^c F_{\xi}(z)$  denotes the Clarke-subdifferential of  $F_{\xi}$  and  $\tilde{\xi}(z_i)$  is an m-1 dimensional Gaussian random vector (familiar from classic results)

### And changeable points?

#### Proposition ([van Ackooij and Minoux(2015)])

Let  $G^q = (V^q, E^q)$ , be the connected q = 1, ..., Q components of the correlation graph and  $(L^q, R^q)$  be the associated bipartition. Let *z* be changeable. Define  $J \subseteq \{1, ..., Q\}$  as the set of all *q* for which either  $|V^q| = 1$  or no changeable arc exists in  $V^q$ . For each remaining  $q \in \{1, ..., Q\} \setminus J$ , pick  $l^q \in L^q$ ,  $r^q \in R^q$  such that  $z_{l^q} \leq z_p$  for all  $p \in L^q$  and  $z_{r^q} \leq z_p$  for all  $p \in R^q$ . If  $R^q$  is empty,  $r^q$  should be interpreted as being "empty". Then the distribution function  $F_{\xi}(z) := \mathbb{P}[\xi \leq z]$  is locally Lipschitz at *z* and  $v \in \partial^c F_{\xi}(z)$ , where for arbitrary *i*=1,...,*m*:

$$v_{i} = \begin{cases} f_{\xi_{i}}(z_{i})F_{\tilde{\xi}(z_{i})}(z_{1},...,z_{i-1},z_{i+1},...,z_{m}) & \text{if} & i \in \cup_{j \in J}V^{j} \\ f_{\xi_{i}}(z_{i})F_{\tilde{\xi}(z_{i})}(z_{1},...,z_{i-1},z_{i+1},...,z_{m}) & \text{if} & \exists q \in \{1,...,Q\} \setminus J, i \in \{I^{q}, \\ 0 & \text{otherwise} \end{cases}$$

(13)

44/56

《曰》《曰》《曰》《曰》《曰》

Moreover  $\partial^c F_{\xi}(z)$  contains at least two elements.

### A final definition

#### Definition

Let  $z \in \mathbb{R}^m$  be arbitrary. Define the set  $\mathcal{E}(z)$  as the set of all v defined according to previous formula, where we enumerate all possible choices of  $l^q$ ,  $r^q$  for each q. For a specific q if  $V^q$  contains a changeable arc with one endpoint in  $L^q$  and the other endpoint in  $R^q$  we adjoin to this set of choices,  $v \in \mathbb{R}^m$ , with  $v_p = 0$  for  $p \in V^q$ .

### The main result

#### Theorem ([van Ackooij and Minoux(2015)]),

Let  $\xi$  be an *m*-dimensional Gaussian random vector with mean  $\mu \in \mathbb{R}^m$  and covariance matrix  $\Sigma$  having all diagonal entries equal to 1. Then the distribution function  $F_{\xi}(z) := \mathbb{P}[\xi \leq z]$  is continuously differentiable if and only if  $z - \mu$  is not changeable.

Moreover  $F_{\xi}$  is locally Lipschitz at z and

$$\partial^{c} F_{\xi}(z) = \operatorname{co}\left(\mathcal{E}(z)\right), \tag{14}$$

46/56

where co(B) denotes the convex hull of set  $B \subseteq \mathbb{R}^m$ .

### Linear maps as a special case: another formula

When seeing the linear situation, i.e.,  $\varphi(x) := \mathbb{P}[A\xi \le x]$ , as a special case of nonlinear *g* we get:

#### Corollary

Let  $\xi \sim \mathcal{N}(0, R)$  for some positive definite correlation matrix R admitting a decomposition  $R = LL^T$ . Fix any  $\bar{x} \in \mathbb{R}^n$  such that  $\bar{x}_j > 0$  for all  $j \in \{1, \dots, p\}$ . Finally assume that any two active rows of the matrix A are linearly independent:

$$Az \leq \bar{x}, A_i z = \bar{x}_i, A_j z = \bar{x}_j, i \neq j \Longrightarrow \text{rank} \{A_i, A_j\} = 2.$$
 (15)

Then,  $\varphi$  is continuously differentiable at  $\bar{x}$  and it holds that

$$\frac{\partial \varphi}{\partial x_j}(\bar{x}) = \int_{\left\{ v \in \mathbb{S}^{m-1} | A_j L v > 0, \bar{x}_j = \hat{\rho}(v) A_j L v \right\}} \frac{\chi(\hat{\rho}(v))}{A_j L v} d\mu_{\zeta}(v) \quad (j = 1, \dots, p).$$
(16)

47/56

			(Sub-)Differentiability	
	00 00000 000	0000 0000000	000 0000000000 0000	
(M-Sub)Differentiabili	ty			
Somo not	ation			

We introduce the following equivalence class within the index set {1,..., p} of rows of the matrix A:

$$i \sim j \iff \exists \lambda \in \mathbb{R} : A_i = \lambda A_j, \ \bar{x}_i = \lambda \bar{x}_j.$$

- By the assumption x
  <sub>j</sub> > 0 for all j ∈ {1,..., p}, i ∼ j implies that λ > 0 in the defining relation.
- Moreover  $i \approx j$  implies that rows  $A_i$  and  $A_j$  of A are linearly independent.

	Differentiability: setting	Differentiability: results	(Sub-)Differentiability		
	00 00000 000	0000 0000000	000 0000000000 0000		
(M-Sub)Differentiabili	ty				
Some notation					

- Denote by  $\tilde{p} \leq p$  the number of different equivalence classes [*i*].
- We may assume (w.l.o.g) that the first  $\tilde{p}$  rows of A belong to different equivalence classes.

Now, for any 
$$i = 1, \ldots, \tilde{p}$$
 that

$$A_{j}z \leq x_{j} \quad \forall j \in [i] \Longleftrightarrow A_{i}z \leq h_{i}(x) := \min_{j \in [i]} \lambda_{j}^{-1}x_{j}.$$
(17)

49/56

• We denote by  $\tilde{A}$  the submatrix of first  $\tilde{p}$  rows of A.

	00 00000 000	0000 0000000	000 0000000000 <b>000</b>	
(M-Sub)Differentiabi	lity			

### A fine characterization of the *M*-subdifferential

#### We can then show

#### Theorem ([van Ackooij and Henrion(2016)])

Let  $\xi \sim \mathcal{N}(0, R)$  for some positive definite correlation matrix R admitting a decomposition  $R = LL^T$ . Fix any  $\bar{x} \in \mathbb{R}^n$  such that  $\bar{x}_j > 0$  for all  $j \in \{1, ..., p\}$ . Then,  $\varphi$  is locally Lipschitz continuous and its Mordukhovich subdifferential can be estimated from above by

$$\partial^{M}\varphi(\bar{x}) \subseteq \sum_{i=1}^{\tilde{p}} \int_{\mathfrak{S}} \frac{\chi\left(\hat{\rho}\left(\nu\right)\right)}{\tilde{A}_{i}L\nu} d\mu_{\zeta}(\nu) \cdot \bigcup \left\{\lambda_{j}^{-1}\boldsymbol{e}_{j}|j\in[i]:\lambda_{j}^{-1}\bar{x}_{j}=h_{i}(\bar{x})\right\},$$

where

$$\hat{
ho}(\mathbf{v}) := \min\left\{ \overline{\mathbf{y}}_j/(\mathbf{A}_j L \mathbf{v}) | j \in \{1, \dots, \widetilde{\mathbf{p}}\} : \widetilde{\mathbf{A}}_j L \mathbf{v} > \mathbf{0} \right\}.$$

and

$$\mathfrak{S} := \left\{ \boldsymbol{v} \in \mathbb{S}^{m-1} | \tilde{\boldsymbol{A}}_i \boldsymbol{L} \boldsymbol{v} > \boldsymbol{0}, \bar{\boldsymbol{y}}_i = \hat{\rho} \left( \boldsymbol{v} \right) \tilde{\boldsymbol{A}}_i \boldsymbol{L} \boldsymbol{v} \right\}.$$
